

Preliminary Amendment  
Attorney Docket No. 043176

**REMARKS**

The above amendment to the claims has been made to incorporate the changes made under PCT Article 34 amendment; to correct the multiple dependency of the claims and to place the application in better condition for examination.

In the event that any fees are due in connection with this paper, please charge our Deposit Account No. 50-2866.

Respectfully submitted,

SPECIFICATION

DATA COMMUNICATIONS TERMINAL

FIELD OF THE INVENTION

The invention relates to a data communications terminal capable of transferring frame data across a data circuit with regulated image and sound qualities and/or at a regulated transfer rate in accordance with the degree of congestion (or availability) of the data circuit.

Deleted: frame

PRIOR ART

There have been disclosed several data communications terminals. For example, Japanese Patent Application Laid Open 2002-34024 discloses a data communications terminal that changes setup conditions of the terminal in accordance with the degree of congestion of a data circuit. Japanese Patent Application Laid Open 2002-55902 discloses a communications terminal having a capability to determine whether the data circuit in use is congested or not by monitoring data transfer time and terminate the data transfer when the data transfer time is larger than a preset period of time. Japanese Patent Application Laid Open 2000-295272 discloses another data communications terminal having a capability to send a test file associated with an original data file across a data circuit to see if the data transfer time exceeds a predetermined time and, if it does, determine that the data circuit is congested. When the data circuit is congested, the data compression ratio of the

original image data is increased or the frame rate is reduced. It is noted that these data communications terminals are all directed to data transfers of image data only, not to image data and audio data, to which the present invention is directed. Note further that prior art mechanisms of determining the degree of congestion rely on the comparison of data transfer time with a predetermined reference time, and that the prior art cannot precisely determine such time varying congestion of a data circuit or cannot transfer image and audio data efficiently with adequate image and sound qualities and/or at an adequate frame rate in accordance with the congestion of the data circuit.

It is, therefore, an object of the invention to overcome these problems mentioned above by providing simple means for efficiently transferring data frames containing both image and audio data while maintaining at least minimum levels of image and sound qualities without waiting for a free data circuit by measuring the degree of congestion (or availability) of the data circuit on the real time basis and varying the image and sound qualities and/or the frame rate of data transfer in accordance with the congestion.

#### DISCLOSURE OF THE INVENTION

In accordance with one aspect of the invention, there is provided a data communications terminal for transferring frame data in sequence to and from another data communications terminal via a data circuit in units of data frames with each data frame amounting to a still picture containing compressed image data of a variable data length and compressed audio data of variable data length, the

terminal having a capability to:

transmit a multiplicity (N) of leading data frames  
with predetermined image and sound qualities and/or at a  
predetermined transfer rate;

measure data transmission time required for the terminal to  
transmit a data frame that precedes the current data frame to thereby  
determine the degree of congestion of the data circuit; and

transmit subsequent data frames with reduced or  
enhanced image and sound qualities and/or at a reduced or  
increased frame rate in accordance with the magnitude of  
the data transmission time.

In accordance with another aspect of the invention,  
there is provided a data communications terminal for  
transferring frame data in sequence to and from another data  
communications terminal (referred to as receiving  
terminal) via a data circuit in units of data frames with  
each data frame amounting to a still picture containing  
compressed image data of variable length and compressed  
audio data of variable length, the terminal having a  
capability to:

transmit a multiplicity (N) of leading data frames  
with predetermined image and sound qualities and/or at a  
predetermined frame rate;

determine the degree of congestion of the data circuit  
based on data reception time required for the receiving  
terminal to receive a data frame that precedes the current  
data frame; and

transmit subsequent data frames with reduced or  
enhanced image and sound qualities and/or at a reduced or  
increased frame rate in accordance with the magnitude of

the data reception time.

In accordance with still another aspect of the invention, there is provided a data communications terminal for transferring frame data in sequence to and from another data communications terminal (referred to as receiving terminal) via a data circuit in units of data with one unit amounting to a still picture containing compressed image data of variable length and compressed audio data of variable length, the terminal having a capability to:

transmit a multiplicity (N) of leading data frames with predetermined image and sound qualities and/or at a predetermined transfer rate;

determine the degree of congestion of the data circuit based on data transmission time required for the terminal to send a data frame that precedes the current data frame and data reception time required for the receiving terminal to receive a data frame that precede the current data frame; and

transmit subsequent data frames with reduced or increased image and sound qualities and/or at a reduced or increased frame rate in accordance with the magnitudes of the data transmission time.

In accordance with a further aspect of the invention, there is provided a data communications terminal for transferring frame data in sequence to and from another data communications terminal (referred to as receiving terminal) via a data circuit in the unit of still picture that comprises of compressed image data of a variable data length and compressed audio data of variable data length, the communications terminal having a further data transfer

capability to measure data reception time to receive a sequential data frame transmitted from said another communications terminal (referred to as transmitting terminal) and send back the measured data reception time to said another terminal.

The data transmission time may be a time interval between the beginning and the end of the transmission of any preceding data frame transmitted by the terminal.

The data reception time may be a time interval between the beginning and the end of the reception of any preceding data frame by the receiving terminal.

The data communications terminal of the invention may be adapted to:

transmit a next data frame  $F(N+1)$  with reduced image and sound qualities and/or at a reduced frame rate based on a determination that the degree of congestion (or availability) of a data circuit has increased (that is, availability has decreased) when the data transmission time  $T_t$  has increased for the currently receiving data frame  $F_N$  as compared with the data transmission time for the preceding data frame  $F(N-1)$ ; and

transmit the next data frame  $F(N+1)$  with enhanced image and sound qualities and/or at an increased frame rate based on a determination that the degree of congestion has decreased when the data transmission time  $T_t$  has decreased for the currently receiving data frame  $F_N$  as compared with the data transmission time for the preceding data frame  $F(N-1)$ .

The data communications terminal of the invention may be adapted to:

and/or frame rate of data frames to be transferred.

The data communications terminal of the invention may be adapted to reduce image and sound qualities and/or frame rate to respective minimum levels while maintaining reproduced images and sounds recognizable.

In a data communications terminal of the invention, quality of image data may be given in terms of compression rate and picture size (which is defined by vertical and horizontal numbers of pixels) of the image data, and sound quality may be given in terms of compression rate of audio data.

#### BRIEF DESCRIPTION OF THE DRAWINGS

The invention will now be described in detail by way of example with reference to accompanying drawings, in which

Fig. 1 is a block diagram representation of a data transfer system for transferring data from a data communications terminal of the invention serving as a transmitting terminal to another communications terminal of the invention serving as a receiving terminal via a data circuit, adapted to determine the degree of congestion of the data circuit from the data transmission time measured by the transmitting terminal.

Fig. 2 is a block diagram representation of a data transfer system for transferring data from a data communications terminal of the invention serving as a transmitting terminal to another communications terminal of the invention serving as a receiving terminal via a data circuit, adapted to determine the degree of congestion of

the data circuit from data reception time measured by the receiving terminal (which is a time for the receiving terminal to receive 1 data frame).

Fig. 3 a block diagram representation of a data transfer system for transferring data from a data communications terminal of the invention serving as a transmitting terminal to another communications terminal of the invention serving as a receiving terminal via a data circuit, adapted to determine the degree of congestion of the data circuit from the data transmission time measured by the transmitting terminal and the data reception time measured by the receiving terminal.

#### MODE FOR CARRYING OUT THE INVENTION

The invention pertains to a data communications for sequentially transferring data in units of data frames from a data communications terminal of the invention serving as a transmitting terminal to another data communications terminal of the invention serving as a receiving terminal across a data circuit, with each data frame amounting to one still picture image data of variable length and compressed audio data of variable length. The above described compressed data frame F of variable length consists of compressed image data Db of variable length and compressed audio data Da of variable length, as shown in Fig. 4(a). The image data Db and audio data are obtained by compressing uncompressed data frame F' of variable length consisting of image data Db' and audio data Da' in a data communications terminal using proper compression methods suitable for the respective data.

As shown in Figs. 1-3, two identical data communications terminals of the invention, one serving as a transmitting terminal 2 and another as a receiving terminal 4, are connected via a data circuit 3. Each of these

terminals has two fundamental capabilities, data transmission capability A and data reception capability B.

Based on the data transmission time  $T_t$  measured by the data communications terminal acting as a transmitting terminal 2 as shown in Fig. 1 or data reception time  $T_r$  measured by the data communications terminal acting as a receiving terminal 4 as shown in Fig. 2, and based on the data transmission time  $T_t$  and data reception time  $T_r$  as shown in Fig. 3, the transmission capability A enables the terminal to determine whether data transmission time and/or data reception time are/is increasing for the current data frame and to transmit a data frame with regulated image and audio qualities and/or at a frame rate based on the determination.

The reception capability B enables the data communications terminal (receiving terminal 4) to measure data reception time  $T_r$  for a data frame received from the transmitting terminal 2 and stored in a received data memory 4A by means of a reception time counter 4B, and send the measured data reception time  $T_r$  to the transmitting terminal 2 using the transmission capability A of the receiving terminal 4 as shown in Figs. 2, 3, and 6.

Details of the transmission capability A of the data communications terminal serving as a transmitting terminal 2 are as follows. Image data  $Db'$  entering an image information input unit 2A and audio data  $Da'$  entering an audio data input unit 2B are integrated into a single data frame  $F'$  and stored in a frame data memory 2C, as shown in Fig. 5. Each uncompressed frame data  $F'$  has a variable length. Each of the data frames  $F'$  is compressed to data frame  $F$

consisting of compressed image data  $Db'$  and compressed audio data  $Da'$  by means of a data frame compression unit 2F based on image and sound quality data (specifying data compression ratio and picture size) prescribed by an image and sound qualities setting/regulating unit 2D. The compressed frame data  $F$  thus formed is once stored in a transmission data memory 2G, and transferred therefrom at the transfer rate (frame rate) set up by a frame rate setting/regulating unit 2E. The image and sound qualities data (specifying data compression ratio and picture size) set up by the image quality setting/regulating unit 2D and the frame rate (transfer rate) set up by the frame rate setting/regulating unit 2E are modified based on the data calculated by an image quality and frame rate calculation unit 2I in accordance with the degree of congestion of the data circuit 3.

It is noted that in regulating the image and sound qualities and frame rate, the regulation of image and sound qualities may be prioritized over the regulation of frame rate. For example, when the data circuit 3 is congested, the image and sound qualities may be dropped to a level at which the image can be recognized and the sound can be audible while maintaining a constant frame rate. The image quality is given in terms of data compression ratio of image data and picture size (or vertical and horizontal numbers of pixels). Sound quality is given in terms of data compression ratio of audio data.

The degree of congestion (or availability) of the data circuit 3 can be determined based on: (1) data transmission time  $T_t$  for sending 1 frame data stored in the transmission

data memory of the transmitting terminal 2 as shown in Fig. 1; (2) data reception time  $T_r$  for storing 1 frame data in the received data memory of the receiving terminal 4 as shown in Fig. 2; and (3) data transmission time  $T_t$  and data reception time  $T_r$ , as shown in Fig. 3. Incidentally, the data transmission time  $T_t$  is defined to be the time interval between the beginning (at time  $t_1$ ) and the end (at time  $t_2$ ) of the transmission of 1 compressed data frame  $F$  stored in the transmission data memory 2G. The data reception time  $T_r$  is defined to be the time interval between the beginning (at time  $t_1$ ) of the reception and the end (at time  $t_2$ ) of storing 1 compressed data frame  $F$  in the received data memory 4A. Although means for measuring these time intervals are necessary, calculations of the time intervals may be carried out by an instruction set of a data transmission program or of a data reception program, so that data communication terminals can be simplified in structure.

Operations of the receiving terminal 2 controlling the image and sound qualities and/or transfer rate (frame rate) of compressed data frames  $F$  will now be described in detail for an instance where the control is based on the data transmission time  $T_t$  in accordance with the first method (1) above.

In the transmitting terminal 2 a transmission time measurement unit 2H measures data transmission time  $T_t$  by measuring the time interval between the beginning (at time  $t_1$ ) and the end (at time  $t_2$ ) of the transmission of 1 compressed data frame  $F$  stored in the transmission data memory 2G,, as shown in Fig. 1 and 5. An image and sound qualities calculation unit 2I calculates a ratio

$T_t(N)/T_t(N-1)$  of the data transmission time  $T_t(N)$  for the current frame  $F_N$  to the data transmission time  $T_t(N-1)$  for the immediately preceding data frame  $F(N-1)$  and determines whether the data transmission time  $T_t$  is increasing or decreasing in accordance with the ratio being larger or smaller than 1, as shown in Fig. 7. When it is determined that the data transmission time  $T_t$  is increasing, the image quality and frame rate calculation unit 2I instructs the image quality setting/regulating unit 2D to increase the data compression ratio and decrease the screen size, and instructs the frame rate setting/regulating unit 2E to decrease the frame rate. When the data transmission time is decreasing, the image quality and frame rate calculation unit 2I instructs the image quality setting/regulating unit 2D to decrease the data compression ratio and to increase the screen size, and instructs the frame rate setting/regulating unit 2E to raise the frame rate. The procedure of the second method (2) after the determination of data reception time  $T_r$  and the procedure of the third method (3) after the determination of data transmission time  $T_t$  and data reception times  $T_r$  are the same as that of the first method (1) as shown in Fig. 8 and Fig. 9, respectively.

In the example shown in Fig. 4(b), of the frame data  $F_1, F_2 \dots F(N-1)$ , and  $F_N$  sequentially transmitted from the transmitting terminal 2, the first and the second data frames  $F_1$  and  $F_2$ , respectively, are transmitted with the image and sound qualities (i.e. data compression ratio and screen size) and at the transfer rate (frame rate) as initially set up by the image quality setting/regulating

unit 2D and frame rate setting/regulating unit 2E, respectively. Subsequent data frames are each transmitted with regulated image and sound qualities and at a regulated transfer rate (frame rate) as prescribed by the image quality and frame rate calculation unit 2I. That is, each of the subsequent data frames  $F3, T4 \dots$  is transmitted with reduced image and sound qualities and/or at a reduced frame rate when a determination is made that the degree of congestion of the data circuit has increased based on the measurement of a data transmission time ( $Tt1, Tt2 \dots$ ) for a respective preceding data frame ( $F1, F2 \dots$ ), but when a determination is made that the degree of congestion of the data circuit has decreased based on the measurement, subsequent data frames are each transmitted with enhanced image and sound qualities and/or at an increased frame rate.

The first and the second data frames  $F1$  and  $F2$  are transmitted with the initially set image and sound qualities and at the initially set frame rate, because measurement and processing of the data transmission time  $Tt1$  for the first data frame and calculations of optimum image and sound qualities and frame rate have not been completed by the time the second data frame  $F2$  is transmitted. Incidentally, in the second method (2) in which the degree of congestion of the data circuit is determined from the data reception time  $Tr$  and in the third method (3) in which the congestion is determined from the data reception time  $Tr$  and the data transmission time  $Tt$ , an extra amount of time is required to send the measured data reception time  $Tr$ . Hence, the determination of the degree of congestion

of the data circuit is made based on the measurements of the data transfer/reception time for a data frame that precedes the current data frame by two frames. Thus, the image and sound qualities and/or frame rate of the subsequent data frames are regulated based on this determination.

The reception capability B of a data communications terminal (serving as a receiving terminal) 4 will now be described in detail below. The reception capability B causes each (compressed) data frame F received from the transmitting terminal 2 to be stored in the received data memory 4A, as shown in Fig. 6. Data reception time  $T_r$  is measured by the reception time counter 4B of the receiving terminal 4 for each data frame. The measured data reception time is returned to the transmitting terminal 2 using the transmission capability A of the receiving terminal 4. Each data frame F stored in the received data memory 4A is reconverted to restore its original format by a data expansion/conversion unit 4C and stored in a frame data memory 4D, and then split up into image data  $Db'$  and audio data  $Da'$ . An image is reproduced from the image data  $Db'$  by an image reproduction unit and displayed on a display 4e. A sound is reproduced from the audio data  $Da'$  by a sound reproduction unit that includes speakers.

#### INDUSTRIAL APPLICABILITY

As described above, the invention may provide a structurally simple data communications terminals capable of efficiently transferring data frames containing both image and audio data via a data circuit while maintaining

certain minimum levels of image and/or sound qualities without waiting for a usable data circuit. This can be done by measuring the degree of congestion (or availability) of the data circuit on the real time basis and altering the image and sound qualities and/or frame rate of a respective data frame in accordance with the degree of congestion.

#### ABSTRACT OF DISCLOSURE

Data communications terminals efficiently transfer image and audio data across a data circuit without being affected by the degree of congestion of the data circuit by altering, in accordance with the degree of congestion, the image and sound qualities and/or the transfer rate of each frame while maintaining minimum preferred qualities of the image and audio data. To do this, a transmitting terminal (2) and a receiving terminal (4) have the same data transfer capabilities. The data transfer capability include a transmission capability that enables regulation of the image and sound qualities and/or frame rate of each data frame to be transmitted from the transmitting terminal (2) to the receiving terminal (4) based on whether the measured data transmission time required to transmit a respective data frame has increased or not. The data transfer capability also includes a reception capability that enables measurement of data reception time required for the receiving terminal (4) to receive a respective data frame transmitted from the transmitting terminal (2) and returns the measured data reception times to the transmitting terminal (2). The transmitting terminal (2) regulates the image and sound qualities and/or frame rate of a subsequent data frame to be sent based on the data transmission time and/or the data reception time.
